***Abstract*—Coding agents now author entire pull requests, and practitioners sharply disagree about what this does to code review: whether it becomes the bottleneck, whether human review is still necessary, and whether it quietly erodes the understanding that it once built. Repository-mining studies measure surface trends but seldom explain the mechanisms beneath them, and the trends themselves prove unstable. A motivating observational analysis of public GitHub activity finds that agent-authored pull requests are reviewed less often, merged several times faster, and discussed less than human-authored ones, yet the direction of these trends flips under different but equally defensible analysis choices, so the traces establish *what* is changing without explaining *why*. To recover the mechanisms, we synthesize practitioner discourse at scale into an *explanatory theory*: we collect 38,709 grey-literature documents (engineering blogs and Reddit threads), filter to those substantively about code review, and code a stratified random sample of 3,100 with an LLM-assisted pipeline, from which we build a causal model of 26 constructs and 67 relationships (64 directed, 3 contested). Its organizing claim is that review is the control point through which a coding agent's effect on software is decided, and that AI does not fix the sign of that effect: the team sets it, through the expertise its humans bring and how it structures the review process. The theory makes the competing positions explicit and turns "AI is changing code review" into falsifiable propositions with named constructs and moderators. As a secondary contribution, we offer the underlying LLM-assisted, grey-literature theory-building method as a scalable template for software-engineering research, with a public implementation.**

I. Introduction

Code review is under pressure from AI, but there is little agreement on how exactly it is changing or what the consequences will be. As coding agents can now author entire pull requests, practitioners have staked out sharply different positions on how this does and should affect review [1]–[3]. A common refrain is that agents now produce code faster than humans can review it, so that review becomes the delivery bottleneck [4], [5]. Some worry about the human cost, that the work shifts people away from an activity many enjoy, coding, toward one many do not, reviewing, with disengagement and burnout risks [6]–[8]. In open source, there is concern about large amounts of AI-generated low-quality contributions flooding projects, overwhelming maintainers and externalizing the cost of review onto them [9]–[11]. Others argue the opposite, that human review may no longer be necessary at all and can be delegated to AI reviewers or folded into the agent's own loop as it checks its own work [12]–[14]. Still others warn of subtler and possibly delayed harms, a creeping cognitive debt or cognitive surrender as developers stop building the understanding that review once demanded [15]–[17].

These effects are not well understood, and they are difficult to study. Repository-mining work has been measuring how AI is changing development activity [18]–[20], including code review, but the results so far are fragmentary and at times conflicting, reporting opposite signs for basic quantities such as how large agent-authored changes are and whether they are merged more or less readily than human ones [21]–[26]. In our own analysis of code review of AI-authored pull requests on GitHub (Section II-B), we find trends, but they are not always stable under different but equally defensible operationalizations, and they do not explain what is happening underneath the surface or adjudicate between the competing causal stories that could produce the same numbers.

Understanding what is actually happening requires causal mechanisms, not just surface trends: How raising one factor changes another, but mediated by a third and moderated by a fourth, and how some of these relationships may feed back on themselves to form virtuous or vicious cycles. Studying mechanisms at that level first requires a theory of them [27], an account of the forces that shape code review in the presence of AI, the variables those forces act on, and how the variables relate. *Building such a theory is the goal of this paper.*

We start from what practitioners have already written publicly about code review in an AI world, whether at length in blog posts and long-form articles or more informally in forums such as Reddit (usually referred to as *grey literature* [28]). We analyze these practitioner accounts to construct a theory of how coding agents reshape code review, centered on factors such as review load, how thoroughly review is performed (its efficiency, depth, and effectiveness), code quality, comprehension debt, and reviewer skill, and on the causal pathways and feedback loops that connect them. The resulting theory (Figure 2) can inform hypotheses that future studies can test, and, more importantly, a framework for designing those studies: A shared vocabulary for defining variables, study designs (for example, causal inference using mediators and colliders), and research questions. We envision that this framework will let researchers untangle the competing underlying effects that are not visible from a surface-level analysis of trends.

We also intend a secondary contribution in *how* we build the theory, using *grey-literature analysis at an unprecedented scale* with LLMs to help handle and code large amounts of data. Rather than conducting a small number of interviews,

we collected 38,709 public documents discussing code review (7,630 web articles and 31,079 Reddit threads). After filtering to those substantively about code review, we coded a stratified random sample of 3,100 documents (1,263 web articles and 1,837 Reddit threads, about 12,000 pages of text; about 500 words/page) using LLMs, inspired by recent work on LLM-driven thematic analysis [29]. We then constructed the theory from the coded data in a largely manual but LLM-assisted process, using LLMs to organize codes in different ways and to search among codes and their corresponding quotes. We believe this could be a model for future repository-mining and theory-building research, making theory construction more accessible and scaling it from a few interviews or a small literature review to the wide range of practitioner perspectives now available at scale.

In summary, this paper makes the following contributions:

- (primary) an explanatory theory of how coding agents reshape code review, with 26 constructs and 67 relationships, that makes competing mechanisms explicit and turns them into falsifiable hypotheses;
- (secondary) a scalable, LLM-assisted methodology for grey-literature theory building that we offer as a template for future work, with a publicly shared, scalable implementation;
- (tertiary) a motivating observational study of how agent-authored pull requests are reviewed in open source today, whose trends corroborate prior findings yet shift direction under defensible analysis choices (Section II-B).

II. Trends in Code Review after the AI adoption

A. Code Review in the Pre-AI Era

Code review is a key practice, with a long history [30]; the lightweight, tool-mediated "modern code review" version dominates today across open source and industry [31]–[33]. Review serves multiple purposes beyond defect detection: knowledge transfer, onboarding, team awareness, and governance [31], [34]–[36], and mining studies link review participation to downstream quality [37]. A recurring theme in this literature is that review is attention-limited and cognitively demanding [38], [39], and that the structural properties of a change (its size, dispersion, and presentation) shape reviewer load and defect detection [40], [41]; metrics such as change entropy and churn concentration characterize how edits distribute across files [42], [43], a tradition our own motivating study (Section II-B) extends to agent-associated changes). Pull-request threads have also long mixed human discussion with machine activity from CI services, dependency updaters, and suggestion bots [44]–[47], and this bot activity can inflate apparent review effort if machine comments are not separated from human scrutiny [48]–[51], a measurement hazard that only intensifies once the *author* is also a machine.

B. A Motivating Study: Review Trends in Agent-Authored PRs

Our theory work grew out of our struggle to interpret observational data. We ran a longitudinal study of how agent-authored pull requests are changing code review. The trends

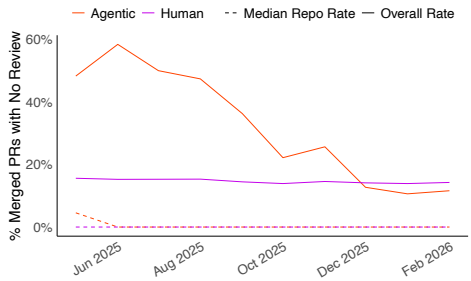

Fig. 1: Proportion of merged PRs with no human review over time, in our sample (solid line: overall rate; dashed line: median of per-project rate). The early agentic no-review rate in mid-2025 falls toward the stable human rate by early 2026.

were clear enough and largely matched prior work, but we could not say what they meant: the same measurements support opposite conclusions about human oversight depending on defensible analysis choices, and they conflict with other recent studies. This pushed us to build a theory of the underlying mechanisms that future, better studies can draw from.

We analyzed the public *Agents in the Wild* corpus [52], re-scraping each repository's full PR history for a longitudinal view (Appendix I gives sampling, author labeling, operationalization, and other details). Consistent with recent snapshot studies (deferred to Section V), agent-authored PRs are merged several times faster than human PRs [21], [22], attract less review discussion in absolute terms and per line changed [21], [23], [53], and are reviewed less independently, with 40.1% examined only by the developer who invoked the agent versus 21.5% of human PRs [53], [54].

Re-scraping full histories also surfaced over-time trends not previously reported. Most strikingly, the share of merged agent-authored PRs receiving no human review falls from over 50% in mid-2025 toward the steady human baseline of about 14% by early 2026 (Figure 1): an initial willingness to merge agent output unchecked gives way to reviewing it much as human PRs are reviewed. This runs opposite to the within-reviewer habituation reported by Yu et al. [26], where oversight weakens over time as approval rises and commenting falls. On the basic question of whether human oversight is consolidating or eroding, studies disagree.

The instability is also within our own data: a finding's direction can reverse under defensible analysis choices. Whether the developer who invoked an agent counts as an independent reviewer or as the author reviewing their own work decides whether independent review of agent PRs sits above or below the human rate. Such studies establish what is changing, not why, and cannot settle which reading is correct. This motivates our theory: a model that locates the direction of an effect in specific practices and context factors rather than the technology, and that guides what to study beyond surface observations about drivers and outcomes.

C. Related Work on Theory Building in Software Engineering

Causal inference should begin with a theory. As Pearl puts it, "data are profoundly dumb" [27]: data can show that two quantities move together, but not why, and no volume of data answers a causal question without a model of the mechanism that produced it. That model must come from outside the data: prior work, domain knowledge, or expert elicitation. Constructing such a model for AI-era code review is our task.

What counts as a theory, and how one is built and judged, is itself a subject of methodological guidance. Gregor distinguishes five types; ours is a *theory for explaining* (her Type II), accounting for how and why rather than predicting what will happen [55], though we cast its claims as falsifiable propositions to seed future studies. Sjøberg et al. and Stol and Fitzgerald set out how theories are constructed and what makes them useful [56], [57]; grounded-theory methodology is standard for bottom-up theory building [58]–[60]. We follow this guidance, presenting our result as constructs and their relationships and judging it by credibility, resonance, and usefulness rather than statistical generalization.

While theory building is well established in our field, the resulting theories are typically distilled from a small, deeply analyzed evidence base: a few dozen interviews or observations, or a handful of teams (for example, a theory of architectural technical debt from 18 interviews [61], or of debugging from seven observed developers [62]), and the few that draw on the literature screen at most a few hundred papers [63]. None engages practitioner discourse at anything close to our scale. We thus make a secondary methodological contribution: showing how to scale theory work to thousands of documents, using LLMs for some mechanical steps.

III. Building a Theory of Post-AI Code Review

A. Methods

We build an explanatory theory of how coding agents reshape code review from *grey literature*: public, practitioner-authored writing about review in the age of AI. We follow the coding stages of grounded theory in the Straussian tradition [59], [60], with a deliberate division of labor: an LLM pipeline does the mechanical work that scale makes infeasible by hand (constructing a corpus, filtering for relevance, and *open-coding* it into a shared codebook), while the authors perform the theory construction, the *axial* and *selective* coding that decides the constructs and their relationships. We code only practitioner documents, not academic (Sec. V); coding both into one codebook would conflate what practitioners believe with what researchers have measured.

Corpus construction. We collect from two registers, tagged with the same AI and review lexicon. The first is **Reddit developer discussion** from the public *arctic_shift* archive [64] (so the frame is fixed and reproducible). Under a stratified purposive design we scan the full 2020–2026 history of 43 subreddits in seven strata: code review (r/codereview, kept in full); version control (r/git, r/github, r/gitlab); general software engineering, the largest (r/ExperiencedDevs, r/programming, r/cscareerquestions); a critical/satirical community; nine language ecosystems (e.g., r/Python, r/rust); AI coding tools (r/ChatGPTCoding, r/ClaudeAI, r/cursor); and broader AI forums (r/OpenAI, r/LocalLLaMA). A thread is kept if its title or body contains *review*, *reviews*, *reviewing*, *reviewer*, *reviewers*, or *reviewed* at a word boundary, with no popularity filter (which would suppress the minority views thematic analysis needs) and only minimal discussion required; each becomes one Markdown document with its comment tree and provenance (**31,079 threads**). The second is **edited long-form writing** (engineering blogs, vendor and practitioner write-ups, tech-press analysis), retrieved through the Exa neural search engine [65] by semantic similarity; to avoid tilting the corpus we issue 68 natural-language queries, each pairing a directional query with its opposite pole (e.g., "How AI coding assistants are changing the code review process" vs. "Why code review has not fundamentally changed despite AI"), over three passes: the open web, the entire Feedspot ranking of software-engineering blogs, and a category-balanced set of institutional domains (engineering-practice media, agent vendors, AI review-tool vendors, developer-productivity research groups). Reversible filters then apply (URL deduplication, removal of very short and long pages, and a block list for document *types* that are never practitioner discourse: academic databases, PDF and book dumps, registries, content farms), yielding **7,630 articles** across 1,437 domains. Together this gives one corpus of **38,709 documents** spanning 2020–2026; Appendix 2 gives the full sampling frame, vocabularies, three-pass design, and corpus-composition figures.

Relevance filtering. The gates are recall-oriented and admit false positives (a performance or product review, "review" meaning *revise*), so we tighten precision in two steps. First, a Reddit keyword gate: outside r/codereview, a thread is kept only if it contains *code* with a review word; web articles, already semantically retrieved, are kept in full. Second, an LLM judge (Google's *Gemini 2.5 Flash*, temperature 0) applies a single neutral, versioned, reasoning-first rubric to the **23,631** candidates (16,001 Reddit threads, 7,630 web articles), retaining **13,469** (57%); a stronger model re-judging a random sample agrees at Cohen's $\kappa = 0.75$ (substantial; Appendix 3). Because agent-related discussion is overwhelmingly recent (the AI-mentioning share of threads rises from under 1% before 2023 to roughly two-thirds in 2026), we restrict coding to **2025–2026**, when agent-authored pull requests became a live concern, leaving about **9,100** documents.

Coding to a shared codebook. From this pool we draw a **source-stratified random sample of 3,100 documents** and code them with *Thematic-LM* [29], a previously-evaluated multi-agent LLM realization of inductive thematic analysis [66] whose *adaptive* codebook is built and revised as data arrive rather than fixed in advance. This is the *open coding* of grounded theory [59], [60], the part we delegate to the LLMs because it is the most labor-intensive and because each code stays anchored to a verbatim quote a human can check.

The coding unit differs by register: each Reddit thread is kept whole to preserve conversational context, while each web article is split into topical segments by an LLM segmenter. Three *coder* agents independently attach one to three short codes, each with a verbatim quote, to every segment; rather than treat coder identity as generic perspective diversity, we instantiate three lenses for the polarized debate: a *neutral* inductive lens, a *critical* lens attentive to how agents and automated review may erode review, and an *appreciative* lens attentive to how they may strengthen it, so optimistic and pessimistic readings enter the codebook by design rather than by the model's default. An *aggregator* then merges near-duplicate codes, and a *reviewer* maintains a single versioned codebook, using sentence-embedding similarity to decide whether each incoming code extends or merges into an existing one. Coding runs in batches of 100 documents (31 in total), each finalizing a codebook revision, and is resumable and tolerant of per-segment failures; all calls use *Gemini 2.5 Flash*. The resulting codebook has **4,838 codes** grounded in **109,951 quotes** from **2,669** sampled documents (1,454 Reddit, 1,215 web). We release a scalable, open-source reimplementation of this pipeline in our replication package; the research context, the three coder identities, and every prompt are in Appendix 4.

From codebook to theory. This is where we draw the line between machine and researcher. Thematic-LM would develop themes in a second automated pass over the codebook, but that presumes a codebook small enough to reason about at once, and with nearly five thousand codes the assumption does not hold. More fundamentally, the step from codes to a causal theory (the *axial* coding that relates categories to one another and the *selective* coding that organizes them around a core [59], [60]) is the interpretive heart of the study, and we did not delegate it. The authors performed it by hand over many iterations, using the model only as an instrument for organizing and retrieving evidence at scale, in the spirit of recent mixed-initiative qualitative analysis [59], [67]–[69].

The construction proceeded in stages. We first asked an LLM to propose the themes latent in the codebook, an initial scaffold rather than a result; the authors then validated and redefined them by hand, splitting overlapping themes, sharpening definitions, and adding constructs we had observed while reading the codebook but the model had missed. A second LLM pass assigned every code to a theme, separating codes that bear on different concerns, and within each theme a further pass proposed sub-themes that the authors again validated, aggregating the codes that make the same claim. These sub-themes gave us an initial vocabulary of constructs and candidate relationships among them. From that draft the authors built the theory through repeated revision (the central work of this study and the part we performed manually), deciding across many passes which constructs to keep, split, or merge and which relationships to assert, reverse, or drop, until the model stabilized. Throughout, we used the codebook as a *search engine*, querying it through the LLM for the practitioner text bearing on a given construct or relationship (for example, every quote about comprehension debt) under varied retrieval strategies, and either confirming a relationship or revising it; at times we hypothesized a relationship from prior understanding (including the empirical findings reviewed in Section II, V), and queried the codebook for the text that would support or contradict it. This interplay of emerging categories and constant comparison against the data, and its willingness to check a posited relationship rather than only let it emerge, is characteristic of the Straussian variant [59], [70]. A closing author audit merges near-duplicate relationships and attaches, to every relationship, its supporting practitioner text and, for the contested relationships, the opposing text as well. The result is the explanatory theory of **26 constructs and 67 relationships** presented next (Figure 2); Appendix 5 gives these prompts and the evidence-tier definitions.

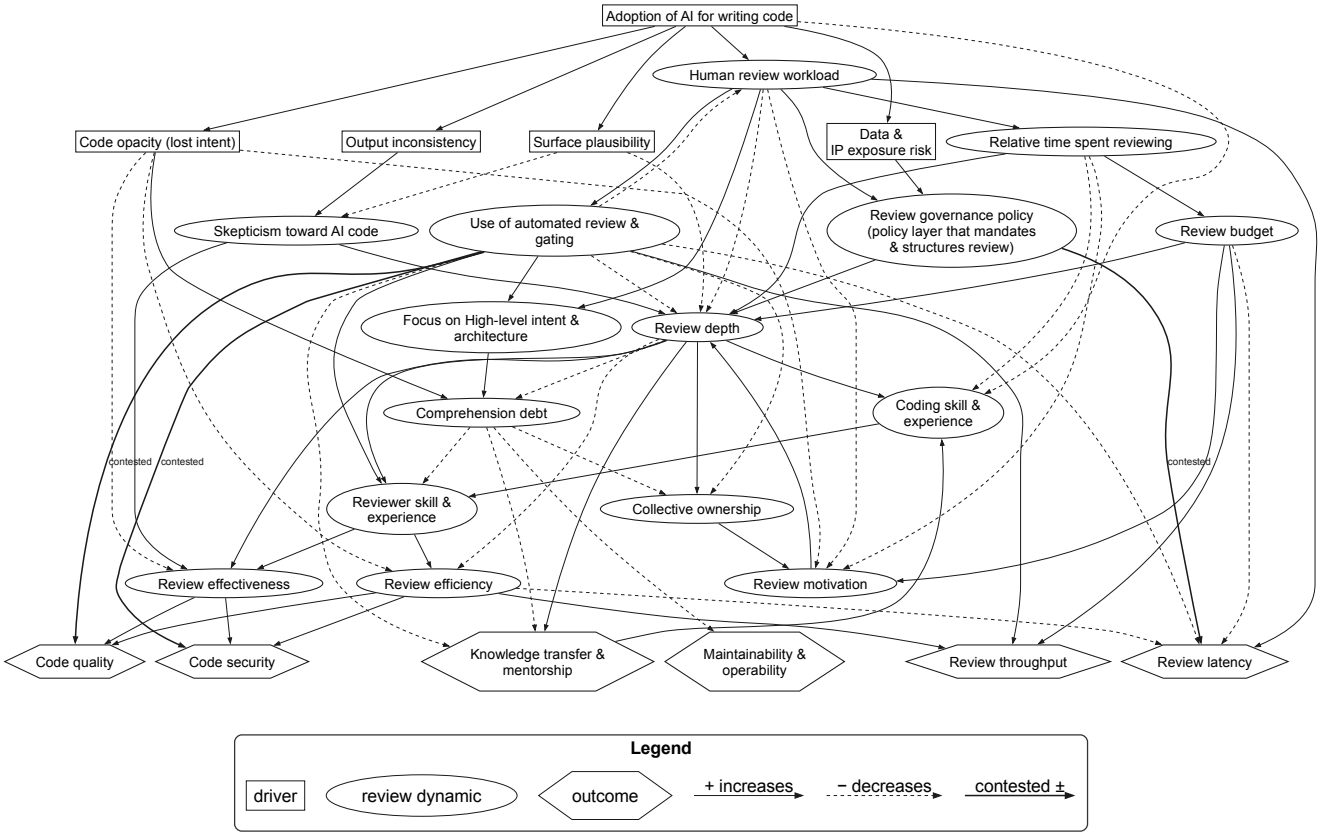

Reproducibility and traceability. Both collection frames (the subreddit strata and inclusion rule; the query list, source passes, and filter specification) and the judge rubric are versioned in configuration, making the corpus reproducible, and an append-only manifest traces every quote in the theory back to its originating document. Each grounded quotation is cited inline by a stable handle (e.g., G2935), and all 3,100 coded documents appear in the *Supplementary Document Index* with each one's handle, dataset identifier, title, and source URL.

1) Limitations: Three threats are specific to this design. First, our sources are written in the age of generative AI, and some may be partly or wholly LLM-generated; we study *discourse* about review, not verified firsthand practice, and read the corpus as practitioner argument rather than ground truth. Second, LLM coding and filtering can miscode, miss, or hallucinate; we mitigate with three independent coders, a verbatim quote behind every code, a separate relevance judge validated against a stronger model, and an author audit of every relationship, though residual error remains. Third, the move from codebook to theory is author judgment at each structural step (by design, since axial and selective coding are the interpretive core of grounded-theory work [59]), so a different team could have drawn the constructs and relationships differently; we constrain this by grounding every one in coded text and attaching opposing evidence to the contested edges, but the result is a *proposed* explanatory theory to be tested, not validated. Finally, grey literature over-represents vocal early adopters and carries vendor advocacy and post-incident hindsight, which we counter through the breadth of thousands of independent sources rather than eliminate.

IV. Results: The Theory

We report the theory not as a list of isolated observations but as a *conceptual theory*: a vocabulary of constructs and the relationships among them that together explain how code review changes when coding agents author pull requests, and what practitioners believe is at stake [56], [57], [71]. In Gregor's taxonomy the result is a *theory for explaining* (Type II), which says *how* and *why* rather than *what will happen* [55]: we make the forces and mechanisms explicit and state them as falsifiable claims, but do not test them or use

Fig. 2: An explanatory theory of how coding agents reshape code review: **26 constructs** and **67 relationships** (64 directed, 3 contested) synthesized from practitioner discourse. The graph reads top to bottom: the *drivers* AI introduces (top), through the reviewer's dispositions, the team's responses, and the five-construct *review act* that the rest of this section unpacks, down to the *outcomes* practitioners care about (bottom). A node's *shape* encodes its role (rectangle: a *driver*; ellipse: a *review-dynamics* construct, i.e., a review-act, reviewer, or team-response construct; hexagon: an *outcome*), and an edge's *line style* encodes the sign of the relationship (solid: increases; dashed: decreases; bold: *contested*, where the sign is set by a moderator).

them for prediction here. Following conventions for reporting qualitative theories in software engineering [60], [71], we present the theory as *constructs* (the boxes of Figure 2) and *relationships* (its directed edges, each a force that fosters or hinders its target), and ground every relationship in coded practitioner text. The theory (Fig. 2) comprises **26 constructs** linked by **67 relationships** (64 directed, 3 contested), distilled from roughly 2,700 practitioner sources and 4,800 codes (cf. Section III-A).

In our setting, relationships are directed, causal claims in the form of *'an increase in construct A* increases *(solid line) or* decreases *(dashed line) construct B.'* In the following description, we highlight a subset of the relationships as numbered, falsifiable *propositions* (P1 . . .) and provide corresponding practitioner quotes – these propositions are the key claims that future work should test and quantify with empirical data, ideally using causal estimands controlling for other constructs in the theory where possible.

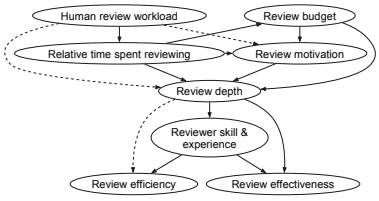

Constructs. Constructs in the theory (Fig. 2) can be divided roughly into three groups:

- **Drivers:** On the one side (top), *drivers* are properties of agent-authored code that practitioners treat as exogenous (coming from the outside, not easily influenced), such as increasing *volume and velocity* of code production due to AI, the *surface plausibility* of AI generated code that reads as clean and idiomatic, the *opacity* of AI generated code due to lost design rationale when no human author formed the intent, and the *data and IP risk* of AI use.
- **Outcomes:** On the other side (bottom), *outcomes* are the consequences practitioners care about, including *review throughput*, *review latency*, *code quality*, *code security*, and *maintainability*.
- **Review dynamics:** In between, the theory describes various constructs related to *review dynamics*, which practitioners can usually influence directly or indirectly. For example, practitioners can choose (within limits) of how deeply to perform a review (*review depth*), how much time to spend on a review (*review efficiency*), or

how to perform reviews (*review policies*, *use of automated review*). They can also influence their own *review motivation* and *reviewer skill*.

These constructs relate to concerns that practitioners talk about, though not always in their words. We often decomposed constructs to emphasize how different forces influence the same concept through different mechanisms – for example, *review throughput* may be increased because a team has more *review experience*, because they lower *review depth* ('rubber-stamping'), or because they bypass manual review with *automated code review*. Each of these factors may again be influenced by several others and multiple constructs have opposite influences on another or form feedback loops. Decomposing this conceptually is a key contribution of the theory.

Increased code volumes are the key driver. Practitioner accounts usually start with the same premise of how coding agents decouple the rate at which code is produced from the rate at which it can be reviewed: *"Reviewer throughput grows linearly with headcount. AI generation throughput grows multiplicatively per developer"* (G2802). If human peer review is pursued for all this code, it raises the *human review load*; without an increase in the *review budget*, this puts pressure on *review efficiency* to review more code in the same time.

The effects of this pressure are commonly discussed among practitioners and usually go through one of two mechanisms: The most common reaction is to perform reviews with less *review depth* (e.g., less attention, looking for fewer problems) so it can be performed quicker, for example, skimming instead of reading: *"if that engineer is reviewing 200 AI-generated PRs a sprint instead of writing code themselves, they're skimming, not reading"* (G2048). Some practitioners also report that the increased load lowers *review motivation*, the willingness to do the job well, as sustained load shades into fatigue: *"Reviewers might keep up for a sprint, but they'll burn out [or] worse, start rubber-stamping reviews"* (G2935). While it speeds up reviewing, it negatively impacts *review effectiveness* and various outcomes we care about, like *code quality*.

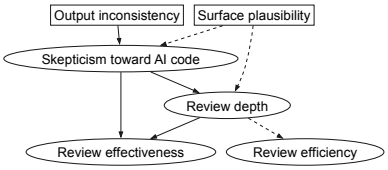

P1. Higher review load decreases review depth, which impacts efficiency and effectiveness.

P2. Higher review load decreases review motivation, which impacts review depth.

Another commonly discussed mechanism is that practitioners increase the *relative time spent reviewing* rather than coding to increase the *review budget* – *"Many software engineers already spend more time reviewing AI-generated code than writing it manually"* (G2045). The worry is that code production consumes the additional review budget even if the team switches most of their time to reviewing (which may further demotivate developers, *"The thing nobody warned me about is the review fatigue. After a few hours reading through AI-generated code, I'm more drained than I'd be after twice as long actually writing code"* (G439)): *"increase code generation speed by 10 to 25 times without proportionally increasing review capacity"* (G2394), while *"The number of reviewers hasn't changed, and neither has the human attention available"* (G2991). Several practitioners predict that human review becomes either shallow or abandoned: *"if your team generates more PRs than your reviewers can thoughtfully evaluate, you either add an automated first-pass layer or you accept that human review becomes performative"* (G3088).

P3. Higher review load increases relative time spent reviewing, which decreases review motivation.

Polished AI code makes reviewing harder. AI code is often polished, clean, and idiomatic – which we call *surface plausibility*. Practitioners report that surface plausibility makes it harder to review as it can disarm the reviewer's defenses: *"polish can lower the reviewer's guard"* (G2222) and *"seniors are rubber-stamping code that looks idiomatic but hides subtle bugs"* (G2208). It lowers effectiveness by camouflage, since the defect is dressed as correct code, *"Plausible violations are harder to catch than obvious ones"* (G2600). Polished code also clears faster, but that speed is a consequence of the dropped attention rather than a separate effect, *"When AI submits polished code, reviewers pattern-match against 'looks professional' and approve faster"* (G2613): the reviewer approves faster because they are scrutinizing less. We posit that *surface plausibility* lowers both *review depth* and thus indirectly *review effectiveness*.

P4. Surface plausibility decreases review depth, which decreases review effectiveness.

The mirror is *skepticism*, the reviewer's disposition to treat AI code as particularly suspicious. Where plausibility disarms, a skeptical reviewer attends harder, *"I've started treating them like code from a junior dev who's super confident, but only moderately competent. I read every line like it's a puzzle"* (G3043), and catches more, because an adversarial frame surfaces what a trusting read passes over, *"the problem is that auth code 'looks correct' to anyone who isn't specifically thinking adversarially"* (G103). The increased depth also makes the skeptic slower, but that slowness is the labor of the added attention, not a separate effect, *"Developers end up spending more time validating that the AI's code actually works"* (G2558).

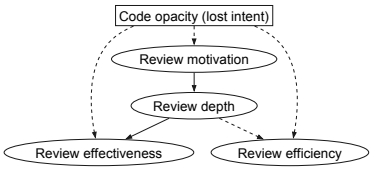

P5. Skepticism toward AI code increases review depth, which increases review effectiveness and decreases review efficiency.

Skepticism may be shaped by external forces. On the one

hand *surface plausibility* lowers it, because polish reads as a safety signal, *"when they see a polished code block, they assume it's safe unless something obvious jumps out"* (G2693). However, observing *output inconsistency*, where AI output differs from run to run, invites an adversarial stance, treating AI like an *"unpredictably unreliable junior engineer whose output you must review with 100% scrutiny, every time, forever"* (G2250).

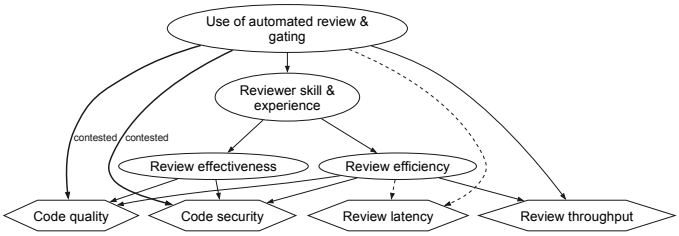

P6. Skepticism can compensate for surface plausibility and is influenced by awareness of output inconsistency.

Reviewing code without understanding intent. Practitioners often discuss how AI-written code arrives without a design rationale, since no human author formed the intent and there is no one to ask why the code is the way it is. This *code opacity* degrades review along three channels. First, it directly lowers *review efficiency*, because an engaged reviewer must reconstruct the intent rather than check against it, *"One reason AI-generated code is harder to review is that you're reconstructing intent"* (G2066). Second, it lowers *review effectiveness* even at full effort, because the yardstick for judging correctness, the intent itself, is gone, *"You can't meaningfully review code you didn't write and don't understand"* (G2413). And finally, it lowers motivation, because reviewing code whose rationale can never be recovered is draining, *"reviewing 5k lines of AI-generated code after the fact is miserable"* (G978).

P7. Code opacity decreases review efficiency, review effectiveness, and review motivation.

The impact of AI for code review is controversial.

It is not possible to separate discussions of reviewing AI-generated code entirely from the rise in AI use for code review as they both evolve rapidly at the same time. As a consequence, *automated code review* has many relations in our theory. AI reviewing can take different forms, from assisting human reviewers, to reviewing for a subset of concerns, to full automation, we need to untangle. First, in our theory most outcomes that practitioners care about, including *review throughput*, *review latency*, *code quality*, and *code security* are influenced through *review efficiency* and *review effectiveness* in the obvious ways (we omit supporting quotes). Fully automating review bypasses the qualities of human review to increase the overall (combined human and automated) *review throughput* and decrease *review latency* (e.g., *"uReview's feedback appears minutes after the commit is posted for review"* (G2304)). The effect of *automated code review* on *code quality* and *code security* is contested. Many argue that given context, the automation catches real defects, *"CodeRabbit catches approximately 82% of planted bugs with a 15% false positive rate"* (G2836), and is strongest where humans struggle, *"CodeRabbit's cross-file contextual analysis is particularly strong for detecting injection vulnerabilities"* (G2027). However, others argue that automated reviews miss what matters and add noise, *"Automated review catches style issues. It misses the 'this will cause a race condition under load' kind of problems"* (G1957), and can manufacture false confidence or raise false alarms, *"LLMs can confidently flag a 'critical SQL injection' in a parameterized query that's perfectly safe"* (G1891).

P8. Fully automating code review increases the overall review throughput and decreases review latency.

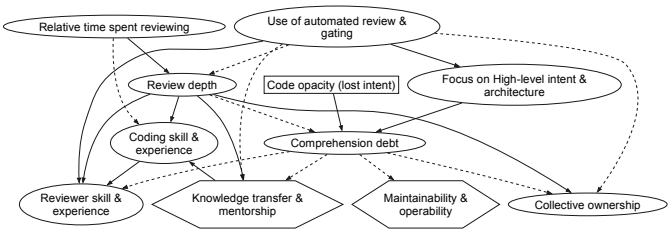

P9. Fully automating code review influences code quality and code security outcomes (direction contested).

Rather than full automation, AI can also be used to assist developers in reviewing code. We describe this in our theory as empowerment of *reviewer skills* (similar to past improvements with better tooling for code review [31]), with indirect effects on *review efficiency* and *review effectiveness* – that is, the same reviewer is more effective at the same time spent or more efficient at the same defect detection rate. Under volume, and with automation handling the line-level pass, the reviewer climbs the abstraction ladder, from reading lines to auditing intent, *"When agents produce thousands of lines per hour, line-by-line review does not scale"* (G2869), until *"You are no longer reading every line. You are now an auditor"* (G2517). The automation helps by clearing routine work before the developer can focus on intent, *"focus on higher-value tasks such as architectural design"* (G2087). A too high-level focus has risks though, leaving the line-level understanding unbuilt, *"We are not reviewing the recipe. We are tasting the dish"* (G2392), so engineers *"are increasingly reviewing outputs instead of understanding behavior end to end"* (G2161), and *comprehension debt* accrues (discussed next) even when attention is high.

P10. AI-assisted code review increases reviewer skills, with positive influence on review efficiency and effectiveness.

P11. Greater focus on high-level intent and architecture, driven by volume and automated review, increases comprehension debt even when review depth is high.

The human costs: comprehension, ownership, and skill.

Many concepts in our theory are influenced directly or indirectly by reviewer skills or motivation, but those are not fixed and static concepts and we need to pay attention to potential feedback loops.

First, *review skill* evolves over time through practice. Higher *review depth* provides more opportunity to learn *"Reviewing AI-generated pull requests develops a critical eye for subtle bugs"* (G2356). Similarly, many argue that *review skills* are downstream from *coding skills* (e.g., *"How can you review what you do not yet know how to build?"* (G2384)), which are honed by spending more time programming (i.e., less *relative time spent reviewing*; *"skill atrophy from reduced practice writing code manually"* (G2501)) and getting constructive feedback (i.e., more *review depth* from others). That is, degrading code review due to pressures from high volume AI-generated code, can undermine the ability to review that code in the future, in a negative feedback loop.

P12. Lower review depth limits growth in reviewer skills.

P13. Lower coding skills undermined by less time coding and receiving low quality reviews reduce review skills.

Second, *review depth* improves *collective ownership* and *knowledge transfer*. The act of attentive review is itself how a team comes to own a change, *"When no human has deeply reviewed the logic, nobody owns it"* (G2538), and how knowledge moves from senior to junior *"The thread between a senior and a junior engineer inside a PR shapes how that junior engineer approaches the next twenty PRs they write"* (G3024). A codebase can thus end up formally merged by many but genuinely owned by no one, with little learning imparted on junior team members. Similarly, automating review with AI undercuts that same human capital in two ways. By lowering *review depth*, the attention that builds *collective ownership*, *knowledge transfer*, and *reviewer skill*, it weakens all three at their source; and by shortcutting the human review arrangement that carried them, it removes them directly, *"AI agent reviewers rarely provide knowledge transfer suggestions"* (G2932).

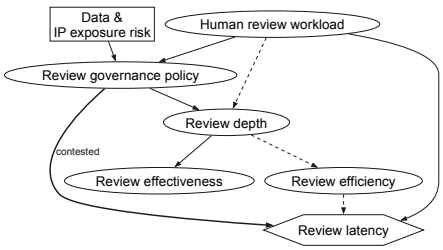

P14. Review depth raises collective ownership and knowledge transfer; automated review undermines them.

Third, beyond direct impacts, the act of low-depth reviews creates *comprehension debt*, undermining the developers' future *review skills* for the code base. Attentive review is how a reviewer forms a mental model of a change, *"That knowledge doesn't come from writing prompts. It comes from reviewing carefully enough to understand"* (G2066); *"juniors who skip the 'read the diff carefully' step never build the mental model"* (G2810). Opacity widens the gap, since part of agent code's rationale was never anyone's to understand, *"Nobody has a working mental model of why the code is structured the way it is"* (G2847). The resulting comprehension debt erodes *maintainability*, *"your ability to debug it, extend it, or refactor it tomorrow is compromised"* (G2026), further hollows *collective ownership*, *"If it is not understood, it is not owned"* (G2161), and further breaks *knowledge transfer* that could teach others and build collective ownership, *"If you're merging PRs you don't fully understand, the bus factor of the project climbs to dangerous levels"* (G2570).

P15. Low review depth and opacity increase comprehension debt, undermining review skill, maintainability, collective ownership, and knowledge transfer.

Here we see the potential for several negative feedback loops, where shallow reviews (e.g., due to volume pressure from AI-generated code) increasingly undermine the ability to perform skilled in-depth reviews. This is particularly important, since AI coding does not just undermine the direct form of building a mental model during coding, but its pressures can also undermine the secondary path of building a mental model during code review.

Governance: Policy levers likely have many direct and indirect effects. As a reaction to changes in code volume and code review, many organizations, both in open source and industry, explore how to formalize behavior expectations with various *review governance policies*, e.g., *"The nine rules below define a modern code review culture designed for high-speed, high-volume change"* (G2552), or mandating human gates on sensitive changes like *"If the code touches security, authentication, or core data structures, it must be written by a human and reviewed by a lead engineer"* (G2339). In addition, also data and intellectual property concerns trigger policy discussions, for example, since agent output *"frequently includes real API keys or test credentials directly in generated code"* (G1967).

A *review governance policy* sets what must be reviewed, by whom, and against what checklist. Its most direct effect is to raise the rigor of review: a policy that demands a careful pass deepens *review depth*, which catches more but takes longer, so it raises *review effectiveness* and lowers *review efficiency*. A reviewer *"spends 45 minutes reviewing it – checking for bugs, edge cases, and code that doesn't match team standards"* (G2527). Beyond mandating steps, a policy can deepen review by assigning accountability: when a team keeps responsibility with people rather than ceding it to the tool, reviewers attend more carefully because they own the output, *"If your team bans 'the AI did it' as an excuse, review quality improves because authors know they own the*

output" (G1872).

P16. Review governance policy raises review depth, which raises review effectiveness and lowers review efficiency.

A policy also sets which changes a human reviews at all, and this is where its effect on *review latency*, the time a change waits to clear, splits, set by the policy's calibration. The aim is to be selective rather than exhaustive, *"The goal isn't to put human eyes on all the code. It's to direct attention where it matters"* (G3058), reserving human sign-off for the changes that need it, *"A few hours of focused audit against the right checklist will find more than weeks of general code review"* (G1893). A risk-tiered policy that gates only material changes and sends routine ones through automated validation clears the bulk of work quickly, *"risk-based change categorisation: only material changes require human sign-off; routine changes flow through automated validation"* (G2335), while a blanket policy that gates every change adds delay, *"Does stricter governance slow down AI code generation? Initially, yes. Enforcement and review add process"* (G2175).

P17. The effect of review governance policy on review latency is contested: its sign is set by policy calibration, lower latency under a risk-tiered policy that gates only material changes, higher latency under a blanket policy that gates every change.

The shape of the theory. The value of the theory lies in the interconnected whole, rather than in any single edge. By decomposing what makes review effective, what makes it efficient, and what lets a change bypass review entirely, we can separate the forces at work and identify the mechanism behind each one. This decomposition reveals a small central core. Most paths run through *review depth* and *reviewer skill*, the attention a reviewer actually applies to a change and the ability they have in doing that effectively. They are the busiest construct in the model, pushed and pulled by many forces and feeding many others, and concepts like *surface plausibility*, *collective code ownership*, and *coding skill* all reach throughput and quality through them and their effects on *review efficiency* and *review effectiveness*. The core also feeds back on itself, through the loops described earlier, such as rubberstamping eroding the foundation for effective future review. A few edges stay genuinely contested, especially regarding what effect AI use has during code review itself.

Status of the theory. Consistent with theory-building in software engineering [57], [71], this is a *proposed* explanatory theory, not a validated one. Its relationships are grounded in what practitioners report and argue, filtered through the lens of the researchers. Its value is conceptual: It supplies a shared vocabulary, makes competing mechanisms explicit and contestable, and turns "AI is changing code review" into a structured set of falsifiable claims and the moderators that would decide them.

V. Related Work on Code Review of AI Code

We deferred related work on code review after AI adoption until after letting practitioners speak, since, as we now show, studies already differ on drivers and outcomes and rarely explore the why.

On the *drivers* of change (top nodes in our theory): coding agents generate code rapidly, with OpenAI Codex alone opening over 400,000 pull requests on GitHub within two months of release [72], raising concern about whether review can keep up [21]. AI-authored code is more verbose [73] and its commit messages more descriptive than rationale-capturing [24], but studies conflict on whether AI-authored PRs are larger [22], [23] or smaller and more focused [22], [24].

On review *outcomes* (bottom nodes in our theory), studies again diverge: agent PRs are accepted at *lower* rates than human PRs in some [21], [23], [72], at *higher* rates for Claude and Codex in others [22], and auto-merged more often but bimodally in yet others [25]. Change size is an established moderator (larger PRs attract more friction and merge less [74], [75]), as are task type (e.g., documentation, CI, bug fixes) [75], [76] and author follow-up [77].

On the review process, most work asks whether PRs are reviewed at all (most are not [21], [53]) and characterizes comment patterns (fewer comments [78], more bot reviews [21], [72], and more steering than evaluating [53]). Several taxonomize the output of code-review agents such as CodeRabbit [72], [79], [80], finding reviews of agent PRs concentrate on style over deeper concerns [79]; norms and policies are still evolving, with a recent overview by Holterhoff [81]. Explorations of deeper mechanisms are rare: studies of rejected agentic PRs find little data to work with [54], [82], and those of agentic PRs merged without comments find no explanation in code quality [83], [84].

Other concepts in our theory have been studied, though mostly in isolation rather than as a connected process: overtrusting AI suggestions [85], [86], judging code by readability, plausibility, or passing tests rather than actual correctness [85], [87], [88], and a trend toward decreasing vigilance or increasing rubber-stamping [26]. Our theory puts such factors into context.

Taken together, this literature is remarkable for its volume, fragmentation, and disagreement. Much of it draws on the same dataset (AIDev) [21] yet reports opposite signs for change size, acceptance, and review effort depending on which agents, repositories, and thresholds fall in scope. Where studies do reach for explanation, they do so locally and tentatively: a fast merge *might* signal superficial review or confidence [21], [26]; light feedback *might* reflect trust or inattention. That gap is what makes the surface trends so easy to read in opposite directions, and supplying the missing theory was the goal of this paper.

VI. Discussion

Theory turns a polarized debate into mechanisms that future studies can test. We are not the first to argue that theory must precede causal inference [27], [56], [57], and our own attempts to study this change without one make the case: in the motivating study (Sec. II-B) the same data supported opposite conclusions under defensible analysis choices, and

the literature was no clearer, reporting opposite signs for quantities as basic as change size, acceptance, and review effort (cf. Sec. V). We can establish what is changing but only speculate why, and our speculation shifted with whichever result we were explaining.

The public narrative is polarized: agents supposedly make review either obsolete or indispensable, faster or more dangerous. Our theory replaces that debate with mechanisms: the effect of agents on review is not monocausal, as external forces pressure the review system without fixing any single outcome. We confirm none of these relationships but lay a foundation for future studies, supplying concepts to operationalize or control for so that a surface metric (a fast merge, few review comments) can be read through the mechanisms beneath it and untangled from the confounders, colliders, mediators, and feedback loops that also shape it. These mechanisms likely explain practitioners' divergent experiences: a reviewer who finds agents have made review faster and one who finds they have made it a rubber stamp need not disagree about the facts, only about which pathway dominated.

Developers have the power to shape the review process in an AI world, but it's not monocausal. The theory shows how AI's effects on peer review can be steered. Most paths to the outcomes practitioners care about run through two central levers, *reviewer skill* and *review depth*: the ability a reviewer brings to a change and the attention they apply to it. Both start from a team's existing position (how well it understands its codebase, how motivated it is to review deeply) but neither is fixed; each is shaped through practice and deliberate decisions. The most consequential is the *use of automated review*, governed by *review policy*: the same lever can focus human attention where it matters or bypass human review entirely. Developers are thus not passive recipients of AI interrupting their work but have agency to shape it at predictable leverage points.

That agency is constrained, however, by an interconnected system in which decisions interact and can create feedback loops: buying throughput by lowering review depth may work in the moment but erodes the reviewer skill, ownership, and knowledge transfer that effective future review depends on, and automation carries the same double edge, accruing comprehension debt even when attention stays high. Whether feedback turns virtuous (skepticism, deeper review, sharper reviewers) or vicious (rubber-stamping, skill atrophy, still shallower review) likely depends on many interacting decisions. The question is thus not whether *AI will ruin or fix code review?* but *which decisions, under which conditions, push the system toward good rather than bad outcomes?*

To design interventions beyond individual decisions like per-project policies, future work could draw on a system-theory lens [89]. System dynamics diagrams resemble our causal models, relating concepts ("stocks") through "flows," but add a time component (delayed flows) and center on feedback loops and equilibria rather than causal inference. System theory also ranks leverage points: adjusting local parameters and regulating negative feedback loops are least effective, while driving positive feedback loops and changing rules and goals are most effective overall [89]. Our theory offers a strong starting point for such a system-thinking approach.

Experienced benefits and limitations of scaling grey literature analysis with AI. This is, in part, a method paper in disguise: scaling grey-literature analysis with AI was itself an experiment. Our primary contribution is the theory of the previous section, but we regard the way we built it, scaling grey-literature analysis far beyond past theory-building studies, as a secondary one. Ideally, every future repository-mining study could cheaply survey the grey literature and build a theory to inform it; we are not there yet, but our approach offers a template for others heading that way, and we share all the infrastructure we created.

Scale was an important goal. First, it increases reach and breadth of voice: thousands of independent sources spanning years and registers, rather than academics or practitioners with reach, or interviewees sampled from a personal network, and that reach comes without the recruitment and interview-time cost to researchers and practitioners.

The costs lie in two places: the tokens for analysis and codebook (about US$0.35 per document across all steps) and the effort of turning the resulting codes and quotes into a theory. Automation worked reasonably well for coding (though merging similar codes could have worked better), but automating the back half, building the theory itself, proved ineffective. To gauge how far automation could go, we extracted causal statements directly from the codebook in one bottom-up pass (prompt in Appendix 5); it yielded **15,029 statements**, but shallow, redundant, and overlapping ones, so we built the theory by hand from the sub-theme claims instead. This is unsurprising: practitioners use inconsistent terms, and the same term for different things, which we had to untangle; at one point a single *review rigor* construct conflated what is now *review efficiency*, *review effectiveness*, *review depth*, and *reviewer skill*, and separating them took sustained interpretive work. The distinction is genuinely useful but not inherent in the documents; we had to impose it by reading in context, keeping interpretation with the human analyst.

Two further notes. On saturation, we suspect 3,100 coded documents exceeded what was needed and far fewer would have sufficed; we scaled because we could. Because the theory-building step was manual over the large codebook rather than automated, we cannot establish after the fact where saturation set in. Second, we coded only the grey literature and brought the academic studies of Section II and Section V in afterward, as comparison, reflecting their different role: grey literature is our object of study, whereas the empirical papers are prior scientific claims that already codify concepts and operationalizations, though our infrastructure could code them just as well.

VII. Conclusion

We synthesized practitioner discourse at scale into a conceptual explanatory theory of how coding agents reshape code

review. Its central claim is that review has become the control point through which an agent's effect on software is decided, and that AI does not set the sign of that effect. The team does, through the expertise its reviewers bring, which AI amplifies, and the review process it adapts in response, which AI rewards; we capture this in three moderators: reviewer expertise and disposition, automated-reviewer capability, and process adaptation. The theory makes the agent-era review debate's competing claims explicit and contestable, surfaces a set of under-attended human costs (comprehension debt, eroded ownership and knowledge transfer, and reviewer deskilling) that compound through reinforcing loops, and turns "AI is changing code review" into a structured set of falsifiable propositions together with the moderators that would let future studies decide them.

Data Availability A fully anonymized replication package https://anonymous.4open.science/r/code-review-theory-replication-package-1230 contains the motivation study, collection and relevance-judging tool, the full document-codebook-theory pipeline, the 3,100 coded documents with grounding quotes, the theory model, all figures, Appendix 1–5, and *Supplementary Document Index* (also part of Appendix 6).

APPENDIX 1
MOTIVATING STUDY: METHODS AND FULL RESULTS

This appendix gives the full data-collection, methods, and results for the motivating observational study summarized in Section II-B.

Data source and repository sampling. The study draws on the public *Agents in the Wild* corpus,[1] which links GITHUB pull requests opened between May 15 and November 12, 2025 to accounts associated with coding agents (e.g., GitHub Copilot, Devin, Cursor, Claude Code, OpenHands) alongside human and bot activity. We retain non-fork repositories with at least ten stars that contain at least one agent-authored and at least one human-authored PR in that window, so that every comparison is made *within* a repository exhibiting both modes of authoring; this leaves **16,317 eligible repositories** from which we sample. Because pull requests nest inside repositories whose baseline activity and agent adoption differ by orders of magnitude, we sample at the *repository* level under a stratified design: repositories are cross-classified by volume bands (quartiles of total PR count, with a fixed-width fallback under extreme skew) and agent-share bins (0–5%, 5–25%, 25–50%, 50–75%, 75–100% agent-associated PRs); a fixed target of 3,000 repositories is allocated across strata in proportion to stratum size by the largest-remainder rule, never exceeding a stratum's population, and repositories are drawn without replacement under a fixed seed. The design favors breadth of coverage across activity and agent-exposure regimes over an exact match to every PR-level marginal. Table I contrasts univariate repository metadata (stars, forks, subscribers, age) for the eligible list versus the drawn sample; the two track closely on central tendency, while star extremes reflect the heavy tails typical of open-source popularity.

Ingest. The *Agents in the Wild* window fixes only which repositories are eligible; for the analysis itself we re-scrape each sampled repository's full pull-request history via the GITHUB API spanning January 2020 through February 2026, so the contrasts are not confined to that window. Although the scrape reaches back to 2020, agent-associated PRs are essentially absent before early 2025, so the agent-versus-human contrasts are driven by activity from roughly May 2025 onward. Of the 3,000 sampled repositories, 2,860 could be retrieved and traced; the remaining 140 could not be located at scrape time (deleted, made private, or renamed since sampling) and are excluded. Each PR is materialized as one row carrying repository linkage, identifiers, timestamps, merge state, changed files, and structured text for commits, comments, and reviews; churn metrics, PR-type labels, and review-derived features are computed in later offline passes. The stratified scrape retains over two and a half million PRs with churn fields and reviewer-side metadata where available.

Rule-based author labeling. Each PR receives an author bucket from deterministic rules rather than a learned classifier. Tool-specific labels are assigned when head-branch naming matches known product conventions, when the author login matches a known integration account, or when first-commit metadata matches known agent or bot patterns; vendor buckets include `codex`, `jules`, `copilot`, `devin`, `cursor`, `claude`, `openhands`, `codegen`, `cosine`, and `tembo`. Actors GITHUB marks as bots without a tool match are labeled `bot`; all remaining PRs default to `human`. The scheme is fast and auditable but imperfect: it can mislabel borderline automation, attribute multi-author work to one login, and under-count agents that avoid these signatures, so "agent" should be read as agent-*associated under our rules* rather than verified end-to-end autonomy.

Measures. The independent variable is author type (agent-associated vs. human). The outcomes describe *whether and how* a pull request is reviewed rather than its internal structure. *Review coverage* records whether a merged PR received any human review at all. *Latency* is time to merge. *Discussion* is the volume of review commentary, reported both raw and normalized by change size as comments per thousand lines modified, since a fixed comment count means something different on a one-line and a thousand-line patch [31]. *Interaction pattern* categorizes who takes part in a PR's review thread under a deterministic rule over participants: no human review, author-only (the only human in the thread is the PR author, alone or alongside a bot), a single reviewer other than the author, or multiple people; this separates review *coverage* from review *independence*. Finally, each PR carries a purpose label (feature, bug fix, refactor, test, CI, and related categories in the spirit of Levin and Yehudai [91]) so that coverage can be read by change type.

Estimation. Because pull requests nest within repositories whose baseline activity and agent exposure differ by orders of magnitude, we summarize each outcome at the *repository* level first and then aggregate across repositories, rather than pooling every PR into a single corpus-wide rate that the largest projects would dominate. Coverage and interaction-pattern outcomes are reported as means of per-project proportions; latency is reported as the median of per-project medians alongside the pooled median. For temporal trends we recompute the same summaries at repository-month granularity: a repository counts as an *adopter* from the first month it records an agent-classified PR, and the headline agent-share series averages repository-level monthly agent fractions rather than a corpus-wide fraction. Our claims are descriptive; the one inferential test we report is a paired Wilcoxon signed-rank test on per-project author-only proportions, which holds repository identity constant by pairing on project. Where an outcome admits more than one defensible operationalization (for example, conditioning on all merged versus only reviewed PRs, or summarizing by mean versus distribution), we report the alternatives side by side rather than privileging one [92], [93].

Limitations. Our operationalization of "agent-authored" PRs relies on account classification, which may not capture all forms of AI assistance (e.g., human PRs with substantial

TABLE I: Univariate repository metadata for the eligible repository list (**Elig.**) versus the stratified sample (**Samp.**), restricted to repositories with at least ten stars (consistent with study inclusion). Subscribers are GITHUB watcher counts.

	Min		Mean		Median		Mode		Max	
	Elig.	Samp.	Elig.	Samp.	Elig.	Samp.	Elig.	Samp.	Elig.	Samp.
Stars	10	10	2,706.1	2,657.4	115	116.5	10	10	431,791	182,688
Forks	0	0	510.4	494.0	29	29	1	1	243,387	46,118
Subscribers	0	0	47.9	47.3	6	6	1	1	9,789	3,563
Age (days)	62	136	1,730	1,776	1,331	1,349	385	136	6,643	6,643

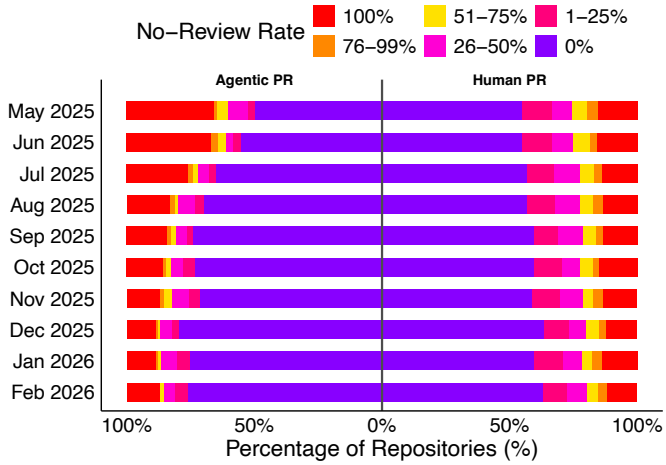

Fig. 3: Distribution of per-project no-review rate over time.

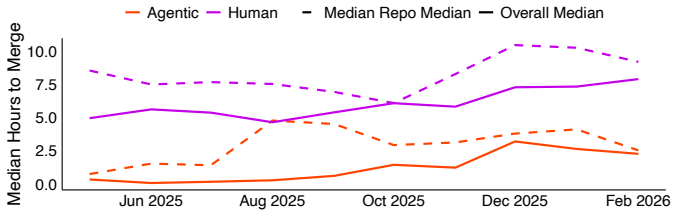

Fig. 4: Median time to merge for human versus agentic PRs over time. Solid line = overall median, dashed line = median of per-project median.

Copilot-generated code). Our review measures (coverage, comment volume, and thread participants) capture observable traces of review but may not reflect its depth, the difficulty of the change under review, or review that took place off-platform. Because the analysis is observational and cross-sectional, unobserved confounding factors may influence both agent adoption and the review outcomes we measure, so the study supports descriptive contrasts rather than causal claims. Our sample is limited to public GITHUB repositories, may not generalize to private or enterprise contexts, and reflects a specific time period given the rapidly evolving capabilities of coding agents. Finally, the sample is built entirely from repositories that already contain agent-authored PRs, and is stratified to span activity and agent-exposure regimes rather than to match every PR-level marginal; it therefore lacks a baseline control group of non-adopting projects, so aggregate contrasts should be read as descriptive of agent-exposed repositories rather than of GITHUB as a whole.

Full results. The findings from our empirical analysis reveal several trends with opposing implications, each of which we outline below. We deliberately scraped each sampled repository's full history back to 2020 to span three eras, pre-AI, non-agentic AI, and agentic AI, but across a range of operationalizations we do not discuss here we found no trends of interest before the agentic era, so we restrict the results to it, roughly May 2025 onward.

No-Review Rate. The share of repositories that merge all agentic PRs without review decreased steadily over the observation period (cf. Figure 3). In May 2025, 34% of repositories with agentic PRs merged all of them with no review; but by February 2026 that share had fallen to 13%, with the majority of the mass shifting into the 0% no-review bin indicating a shift in practice towards reviewing agentic PRs.

Despite the clear decreasing trend in no-review rates for agentic PRs across the projects in our sample, it is also worth noting that merging PRs with no review appears to be a minority behavior to begin with generally speaking: the median per-project no-review rate is near 0% for both author groups in every month (cf. Figure 1, dashed lines), and the overall agentic no-review rate falls from over 50% early in the window to roughly 12% by February 2026, approaching the stable human rate of about 14% (cf. Figure 1, solid lines). The human no-review rate holds relatively stable throughout the observation period.

Among projects that merge PRs without review, no-review rates appear to differ by PR type: agentic PR no-review rates vary widely by PR type (test 69%, refactor 41%, bug fix 25%) while human rates are nearly flat (feature 8% – CI 14%), suggesting that projects triage which agentic changes to review by perceived risk rather than skipping review indiscriminately.

Takeaway. Review coverage of agentic PRs is lower but improving over time, while review coverage of human PRs remains stable.

Review Speed and Thoroughness. In every month of the observation period, the median time to merge is lower for agentic PRs than for human PRs, both pooled across all merged PRs and at the per-project level (cf. Figure 4). Merge times lengthen for both groups across the window: the agentic median climbs from minutes early in the window (roughly 20 minutes in May 2025) to 2–3 hours by early 2026, while the

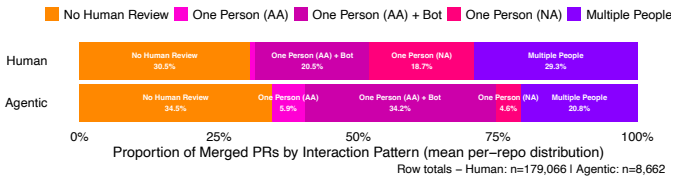

Fig. 5: Mean per-project interaction pattern distribution by PR author group.

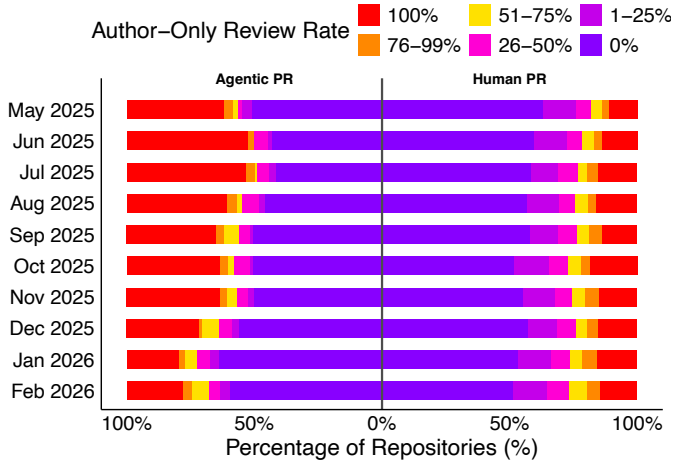

Fig. 6: Distribution of per-project-month author-only review rate among PRs that received any human review, over time.

human median rises from about 5 to 8 hours. The relative gap therefore narrows substantially, from more than tenfold to roughly threefold, even as the absolute gap of around 5 hours persists.

Agentic PRs also accumulate less discussion on their way to merging. Half of agentic PRs (50.2%) receive no review comments at all, compared to 37.9% of human PRs, and normalizing comment counts by change size, human PRs are more often heavily discussed (34.5% versus 27.8% exceed 20 comments per thousand lines modified). Taken together, agentic PRs spend less time in review and attract less commentary while there, both in absolute terms and per line changed.

Takeaway. Agentic PRs move through review substantially faster, with less discussion per line changed, though the speed of agentic PR review is slowing down.

Independent Review and Interaction Patterns. Averaging per-project proportions of each interaction pattern, review coverage is similar across author groups: on average, 34.5% of a project's agentic PRs and 30.5% of its human PRs are merged with no human review (cf. Figure 5). This per-project, whole-window average sits above the pooled end-of-window no-review rate reported earlier: it weights every project equally rather than by PR volume, and it averages over the entire window, including the early months when most agentic PRs went unreviewed. However, the composition of the review that does occur appears to differ.

Author-only review, in which the only human in the thread is the PR author, alone or alongside a bot, accounts for 40.1% of agentic PRs versus 21.5% of human PRs, while review by a single person other than the author accounts for 4.6% versus 18.7%, and review involving multiple people for 20.8% versus 29.3%. These results indicate review of agentic contributions appears less collaborative relatively speaking. While human PRs routinely bring a second person into the discussion, agentic PRs are most often examined only by the person who invoked the agent. A paired Wilcoxon signed-rank test on per-project author-only proportions confirms the difference ($k = 1{,}553$, $V = 418{,}564$, $p < 0.001$, $r = 0.42$); pairing on project holds repository identity constant, so the gap is not attributable to between-project differences.

However, within the subset of merged PRs with any human review, the share of repositories in which every reviewed agentic PR involves only its author also declines modestly over the window, though far less sharply than the no-review rate (cf. Figure 6): independent review of agentic code is growing, but most of the apparent movement appears to reflect more agentic PRs being reviewed at all rather than more people joining the reviews that happen.

Notably, Figures 5 and 6 support different headline conclusions from the same data. When averaging per-project proportions (Figure 5), only about a quarter of agentic PRs involve any human beyond the author. Yet when conditioning on reviewed PRs and binning per-project monthly rates (Figure 6), roughly half of project-months have no author-only reviews at all, suggesting projects that review agentic code routinely involve a second person. Both operationalizations are defensible; they differ in conditioning (all merged PRs versus reviewed PRs), unit of analysis (project versus project-month), and summary statistic (mean versus distribution). The ambiguity extends to the construct itself: if the agent is treated as the author, the human who invoked it is a second, independent set of eyes, and independent review has become more common in agentic PRs than it was for human-authored PRs according to Figure 5. However, if the agent is treated as a tool, that same human is the author reviewing their own work, and independent review has sharply declined.

Takeaway. The review agentic PRs receive is less independent and involves less between-human collaboration.

Summary. Many of the identified trends oppose one another. Review coverage of agentic PRs improves steadily while independent review of them grows only modestly; agentic PRs continue to merge several times faster than human PRs even as merge times lengthen for both groups and the relative gap narrows; review discussion on agentic PRs is thinner both in absolute terms and per line of code. Which story the data tells depends on defensible analysis choices [92], [93]; some operationalizations indicate projects are folding agentic contributions into existing review practices and workflows, while others indicate that most agentic code is reviewed by the agent's operator, or by no humans at all. The traces establish what is changing, but not why, and the data alone cannot adjudicate between these scenarios; doing so requires a theory of what review of agent-authored code is for, what

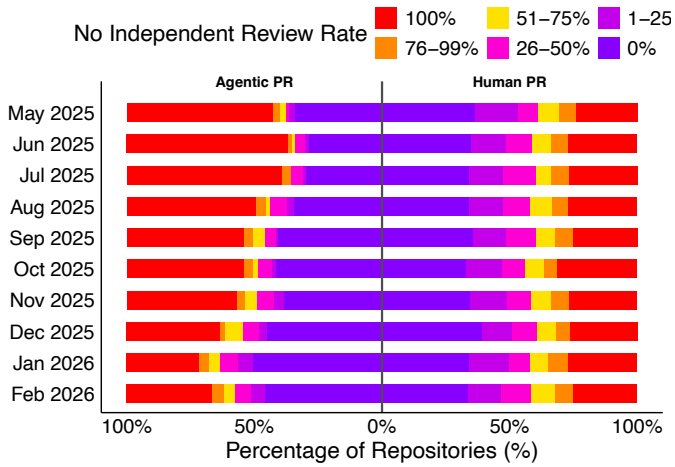

Fig. 7: Distribution of the per-project no-independent-review rate over time (the share of a project's reviewed agentic PRs examined only by their author).

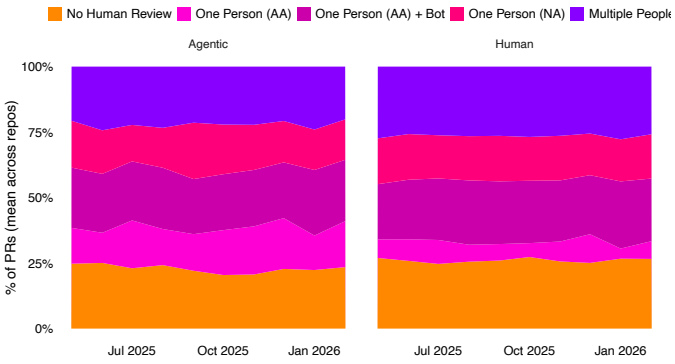

Fig. 8: Mean per-project interaction-pattern distribution by PR author group over time.

counts as review, and which of these changes carry practical consequences for the defect-detection and knowledge-sharing functions practitioners value review for [31].

Additional temporal figures. Figures 7–9 give three repository-month views that complement the cross-sectional contrasts in Section II-B: the per-project no-independent-review rate over time, the mean per-project interaction-pattern mix over time, and the rate of PRs with a participant beyond the author over time. They are descriptive and not referenced by a specific claim in the main text.

Appendix 2
Theory Building: Corpus Construction

Reddit sampling frame. Table II lists the seven strata, their subreddits, and the threads collected from each under the review-word inclusion gate. A thread is kept if its title or body contains any of *review*, *reviews*, *reviewing*, *reviewer*, *reviewers*, or *reviewed* at a word boundary (r/codereview is kept in full). Whether a thread mentions AI is recorded as a tag, never used to include or exclude, using a vocabulary of tool

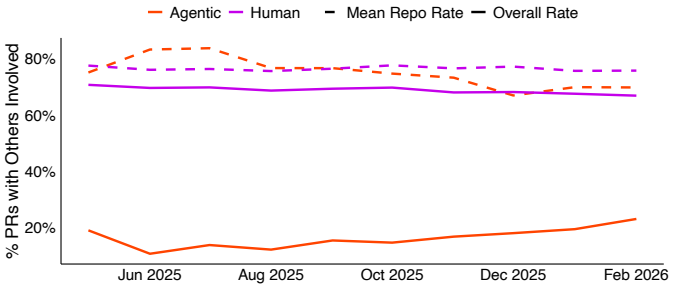

Fig. 9: Proportion of merged PRs with a participant beyond the original author over time. Solid line: overall rate; dashed line: mean of per-project rate.

TABLE II: Reddit sampling frame: seven strata, 43 subreddits, threads collected under the review-word gate (2020–2026).

Stratum	Representative subreddits	Threads
code-review native	r/codereview	541
VCS workflow	r/git, r/github, r/gitlab	904
SE practice	r/ExperiencedDevs, r/programming, r/cscareerquestions, r/devops, r/webdev, . . . (13)	14,717
SE critical	r/programmingcirclejerk	25
language ecosystems	r/Python, r/rust, r/golang, r/javascript, . . . (9)	3,772
AI coding tools	r/ChatGPTCoding, r/ClaudeAI, r/cursor, r/GithubCopilot, r/vibecoding, r/AI_Agents, . . . (8)	7,660
AI general	r/OpenAI, r/LocalLLaMA, r/ArtificialInteligence, r/singularity, . . . (8)	3,460
Total	**43 subreddits**	**31,079**

and concept terms (Copilot, Cursor, Claude, Codex, Devin, Windsurf, Codeium, Aider, CodeRabbit, ChatGPT, Gemini, LLM, AI-generated, coding agent, agentic, vibe coding, and related forms).

Web retrieval design. The web register is retrieved through the Exa neural search engine [65] with 68 natural-language queries, each directional query balanced by its opposite pole. Every query is run through three passes, each with its own 100-result budget: *broad* (the open web, no domain restriction; 2,509 kept), *feedspot* (the entire Feedspot "Best Software Engineering Blogs" ranking of 52 domains, taken wholesale; 2,658 kept), and *curated* (39 institutional domains chosen by category: engineering-practice media, the agent vendors under review, AI review-tool vendors, and developer-productivity research groups; 2,463 kept). Raw results are written first; a reversible filter then deduplicates by URL, drops pages under 150 or over 15,000 words, and blocks document types that are never practitioner discourse (academic databases, PDF and book dumps, registries, content farms). This yields 7,630 articles across 1,437 domains.

Corpus composition. Figure 10 shows the collected corpus by platform, Reddit stratum, year (AI-mentioning vs. all), and top

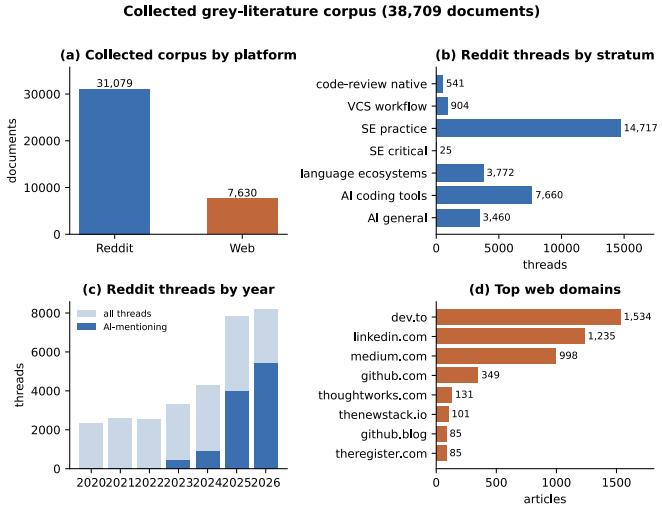

Fig. 10: Collected grey-literature corpus (38,709 documents): composition by platform, Reddit stratum, year, and top web domain.

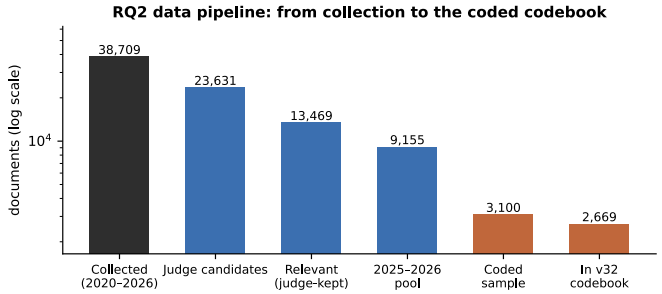

Fig. 11: Theory-building data pipeline (log scale): collection, the relevance-judge candidate and kept sets, the 2025–2026 pool, the coded sample, and the documents represented in the final codebook.

web domain; Figure 11 shows the full pipeline from collection to the coded codebook.

Appendix 3
Theory Building: Relevance Judge

The precision filter (Section III-A) runs the prompt below over the 23,631 candidate documents (the Reddit code+review subset plus all web articles) with *Gemini 2.5 Flash* at temperature 0, retaining the verdict, rationale, and full response per document. It keeps 13,469 documents (57.0%: Reddit 9,241 of 16,001; web 4,228 of 7,630). A re-judgment of 885 documents by a stronger model agrees at Cohen's $\kappa = 0.75$ (substantial; 87.9% raw agreement).

```
You are an expert empirical software-engineering
researcher and a precise data
classifier. For the document below, decide whether
it is relevant to the topic of
CODE REVIEW.

Code review is the software-engineering practice in
 which a developer's proposed or
written code is deliberately examined (by other
engineers, by the author, or by
automated and AI tools) to assess its correctness,
quality, and maintainability and
to give feedback, typically before the change is
merged into a shared codebase. It
is fundamentally a collaborative quality-assurance
and knowledge-sharing activity.
As a topic it encompasses the act of reviewing code
, the reviewers and authors
involved, the process, norms, and tooling that
surround it, and how the practice is
changing and with what consequences.

Mark the document RELEVANT (true) only when it
substantively engages with code
review in this sense: code review, or some facet of
 it, is the document's focus or a
substantive part of its discussion, rather than a
passing or incidental mention.
Apply this judgement regardless of stance, length,
or format, and whether or not
automated or AI tools are involved.

Mark it NOT RELEVANT (false) when the document is
essentially about something else,
even if the words "code" or "review" appear in
another sense, for instance a
performance or product review, "review" used to
mean revising or studying, generic
coding or debugging help with no review angle, or
text that merely mentions code
review in passing.

Judge only from the text provided (it may be
truncated). Respond with a single JSON
object containing, in this order: "rationale" --
one sentence explaining the
decision; "relevant" -- true or false; and "
confidence" -- one of "high", "medium",
or "low" in that decision.
```

Appendix 4
Theory Building: Coding Pipeline

We code a source-stratified random sample of 3,100 documents (1,837 Reddit threads, 1,263 web articles; 2025: 1,059, 2026: 1,999; about 12,000 pages) with the Thematic-LM multi-agent design [29]. Each Reddit thread is one coding unit; each web article is split into topical segments by an LLM-driven segmenter. Figure 12 shows the coded sample's composition. All coding-stage LLM calls use *Gemini 3.1 Flash Lite*; the segmenter uses *Gemini 2.5 Flash Lite*. Coding runs in batches of 100 documents (31 batches), finalizing a codebook revision after each; the final codebook holds 4,838 distinct codes grounded in 109,951 quotes from 2,669 of the sampled documents.

Research context given to every agent.

```
This is a thematic analysis of how the code review
process is changing, especially
with the arrival of AI coding agents, and what the
consequences of that change are.

Code review is the software-engineering practice in
 which a developer's proposed or
written code is deliberately examined (by other
engineers, by the author, or by
```

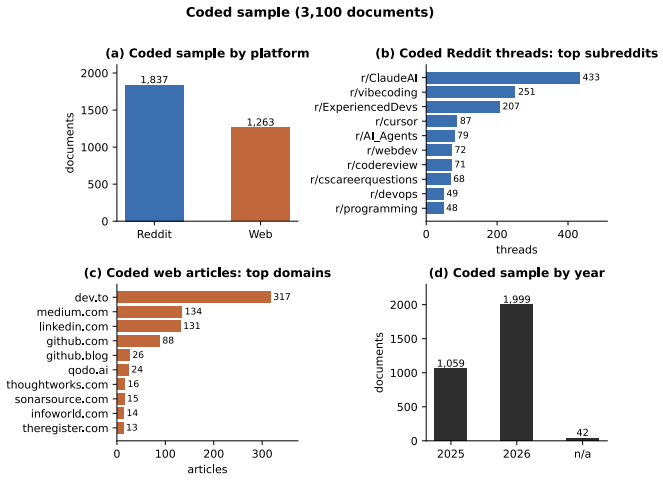

Fig. 12: Coded sample (3,100 documents): composition by platform, top subreddits, top web domains, and year.

```
automated and AI tools) to assess its correctness,
quality, and maintainability and
to give feedback, typically before the change is
merged into a shared codebase. It
is fundamentally a collaborative quality-assurance
and knowledge-sharing activity.
As a topic it encompasses the act of reviewing code
, the reviewers and authors
involved, the process, norms, and tooling that
surround it, and how the practice is
changing and with what consequences.

Code from any period is in scope, whether or not it
 mentions AI, because the aim is
to characterize this change over time and its
consequences rather than to study AI
for its own sake. Material that does not bear on
the practice of code review is out
of scope.
```

The three coder identities. The three coders read every segment through deliberately contrasting analytic lenses:

```
[Neutral] An empirical software engineering
researcher coding inductively in the
grounded-theory tradition, building codes bottom-up
 from the participants' own
words, without preconceived categories or any prior
 view on whether AI helps or
harms code review, attentive both to the process
and practice of code review
(workflow, effort, norms, standards, roles, tooling
, the speed and volume of
changes) and to its human and social dimensions (
trust, accountability, skill,
learning, collaboration, and the relationships
among the people and tools
involved), and to how all of these are shifting.

[Critical] An empirical software engineering
researcher reading the data through a
critical lens, attentive to ways AI coding agents
and automated review may erode
code review, including its quality, the depth of
understanding it provides, trust,
and accountability.

[Appreciative] An empirical software engineering
researcher reading the data through
an appreciative lens, attentive to ways AI coding
agents and AI review tools
strengthen and augment code review, including speed
, coverage, leverage, and new
capabilities.
```

Segmenter prompt (web articles).

```
You segment documents into topical sections for
qualitative analysis. You receive a
document with each line prefixed by its line number
. Identify the line numbers where
major topic shifts occur. Each segment must be at
least paragraph-length (several
sentences); prefer fewer, larger segments over many
 small ones. Shorter documents
have 1-5 segments, longer documents can have 10 to
50 segments, rarely much more
than that. A boundary marks a genuine shift in what
 is being discussed, not a minor
turn within the same topic. The first segment must
start at line 1. For each
segment, give its start_line and a 3-8 word title
describing its topic.
```

Coder prompt.

```
You are a coder in thematic analysis. When given a
text segment, write 1-3 codes for
the segment. The code should capture concepts or
ideas with the most analytical
interest, relevant to the research focus.

For each code, provide a short description (one
sentence) of what the concept means
as a general analytic category, and extract one or
more quotes from the segment
corresponding to the code. Each quote needs to be
an extract from a sentence --
copied verbatim from the segment, not paraphrased.

When an existing code in the codebook fits, reuse
its exact label.

If the segment does not address the research focus,
 return an empty list of codes.
Do not invent codes to cover off-topic material.
```

Aggregator prompt.

```
You are an expert qualitative researcher
responsible for organizing codes from
multiple coders. Your task is to identify codes
with similar meanings that should be
merged, while retaining codes that represent
distinct concepts.

Guidelines for Code Aggregation:
1. Semantic similarity: Merge codes that capture
the same underlying concept
2. Preserve nuance: Keep codes separate if they
capture different aspects
3. Create clear labels: When merging, create a
clear label for the merged code
4. Document decisions: Explain why codes were
merged or kept separate

Respond with JSON listing merge groups (each with
merged_code, original_codes,
rationale) and retain_codes (kept separate,
unchanged).
```

Reviewer prompt.

```
You are an expert qualitative researcher
responsible for reviewing codes and
maintaining codebook quality. Your task is to
evaluate aggregated codes and decide
whether to add them to the codebook, merge them
with existing codes, or reject them.

Guidelines: (1) Quality check -- codes are clear,
meaningful, well-defined;
(2) Consistency with existing entries; (3)
Redundancy -- does it duplicate existing
concepts; (4) Relevance to the research questions.

Decision options: add_new, merge_existing (specify
target), or reject. Respond with
JSON: decision, merge_target (if merging),
rationale.
```

APPENDIX 5
THEORY BUILDING: FROM CODEBOOK TO THEORY

Theme development is manual but LLM-assisted (Section III-A). For each analytic lens, an LLM proposes candidate themes as causal *claims* over the full codebook; the authors validate and redefine them; a further pass derives *sub-themes* within each theme and assigns every code to one; and the resulting sub-theme claims are then grounded by querying the codebook as a search engine. The theme-proposal and sub-theme prompts that drive this are below. We separately tested a more direct route, extracting causal statements straight from the codebook in a single bottom-up pass over the codes, whose prompt and outcome are given at the end of this appendix.

Theme-proposal prompt.

```
You adopt the following analyst perspective (
verbatim, the same perspective used
during coding): {lens}

From that perspective, you are doing reflexive
thematic analysis of a large corpus
(Reddit discussion and web articles, 2025-2026) to
answer this research question:
{research question}

Below is the full codebook from an earlier coding
pass: every code, with the number
of supporting quotes in brackets (a rough salience
signal). Read it as a whole.

Propose 6 to 10 candidate THEMES that answer the
research question from your lens.

What a theme is, and is NOT:
- A theme is a PATTERN OF SHARED MEANING organized
around a central concept -- an
  analytic CLAIM that says something interesting
  about how review is changing and
  with what consequence. Write each title as a
  claim/argument, e.g. "The bottleneck
  shifts from writing code to reviewing it", NOT a
  topic label like "AI tooling".
- A theme CUTS ACROSS many codes; it is not a
single code renamed, and not a
  category of similar codes.
- Capture the CHANGE as the data describes it (a
from -> to shift) and its
  CONSEQUENCE. The corpus is all 2025-2026, so the
  change is what participants
  RECOUNT/EXPERIENCE, not a time trend.

For each theme give: a claim-style title; a one-to-
two sentence claim; the central
organizing concept; the from->to shift; the
consequence; and a brief note of which
parts of the codebook it draws on. Use only what is
 supported by the codebook.
```

Sub-theme prompt. Within each theme's codes, an LLM derives the sub-theme *claims*; a short follow-up pass then assigns each code to its single best-fitting sub-theme.

```
You are analysing the codes within ONE category of
a thematic analysis of
practitioner discourse (Reddit + web, 2025-2026).
Research question (scope):
{research question}

Category: "{category name}" -- {category
description}

Below are the codes assigned to this category (with
 supporting-quote counts).
Identify the recurring SUB-THEMES -- the distinct
claims or patterns these codes
collectively express within this category.

Rules:
- A sub-theme is a specific CLAIM or pattern the
codes make (e.g. "AI introduces new
  security vulnerabilities", or "AI-generated code
  adheres better to standards").
- COMPETING or OPPOSING claims must be kept as
SEPARATE sub-themes -- do not merge
  "AI improves X" with "AI harms X". Surface both
  sides exactly as the codes express
  them; do not impose a direction or balance.
- Aim for a handful (about 4 to 8) of sub-themes
that together cover the codes; each
  substantive and distinct.
- Derive them strictly from what the codes say.

For each sub-theme: a stable id (s1, s2, ...); a
clear claim-style statement; a
one-sentence description; and inclusion criteria
for assigning codes to it.

CODES:
{codes with supporting-quote counts}
```

Direct causal extraction (tested alternative). As an alternative to the theme and sub-theme route above, we tested extracting causal statements directly from the codebook in a single bottom-up pass over the codes. It produced 15,029 statements, but with many shallow, redundant, and overlapping claims, so we built the final model from the sub-theme claims above rather than from this direct extraction.

```
We study ONE phenomenon: software teams
increasingly use AI coding agents to WRITE
code, and we want the impact on the CODE REVIEW
PROCESS. Keep two settings SEPARATE:
- AUTOMATED code review: AI / tools acting as the
reviewer (AI reviewing code).
- MANUAL code review: humans reviewing code,
especially AI-written code.

Below are practitioner-derived CODES (each a
recurring idea distilled from online
discourse, 2025-2026) with supporting verbatim
```

```
QUOTES. For EACH code, extract EVERY
distinct CAUSAL STATEMENT it genuinely supports
ABOUT THE CODE REVIEW PROCESS or its
consequences.

A causal statement is: SUBJECT (the cause/driver)
--RELATION--> OBJECT (the affected
aspect of review, or a downstream consequence).

For each statement provide:
- code_id (the code it came from)
- subject, relation (a short causal verb phrase:
increases, reduces, erodes, enables,
  triggers, shifts, requires, degrades, improves,
  replaces, obscures, accelerates),
  object (concise noun phrases)
- review_type: "automated" | "manual" | "both" | "
general"
- topic: one of [process, reviewer-load, trust-
verification, rigor, defect-quality,
  security, speed-throughput, knowledge-transfer,
  team-awareness, reviewer-skill,
  accountability, governance, tooling, cost,
  reviewer-role]
- polarity: "benefit" | "harm" | "neutral"
- quote: ONE verbatim supporting quote, copied
exactly from the code's quotes.

Rules:
- ONLY statements about the code review process or
its consequences (NOT generic
  commentary about AI or coding in general).
- Ground every statement in the quotes; never
invent. If a code supports no causal
  statement about review, omit it.
- A single code may yield MULTIPLE statements,
INCLUDING OPPOSING ones, keep them all.
- Be specific and faithful to what the code/quotes
actually say.

CODES:
{codes with verbatim quotes}
```

Evidence tiers. Every relationship in the theory is tagged by how it is grounded: *quote-grounded* (stated outright in practitioner text), *read-into* (a ceteris-paribus reading in which the variables move together but the link is not stated as such), and *by-definition* (the internal wiring of the five-construct review act, which holds by how the terms are defined). The three contested relationships additionally carry opposing practitioner text, since their sign is set by a moderator rather than fixed.

APPENDIX 6
SUPPLEMENTARY DOCUMENT INDEX

This index lists the 3100 coded grey-literature documents that ground the theory (RQ2). Each carries a stable handle G#; in-text grounded quotations cite these handles. The *doc id* column is the identifier in the released dataset. Sorted by *doc id*. Non-ASCII characters in titles are transliterated.

Web sources were collected through the Exa neural search index, which captures each page's text content at retrieval time. For a small number of sources, most notably LinkedIn posts, this captured text may not be directly visible to a visitor following the live URL, since the page can render its body dynamically or gate it behind a sign-in. In such cases the URL identifies the source document, while the exact quoted text comes from the content indexed at collection time rather than the page's live rendered view.
